Optimal Index Codes With Near-Extreme Rates
Son Hoang Dau, Vitaly Skachek, Member, IEEE, and Yeow Meng Chee, Senior Member, IEEE

Abstract—The min-rank of a digraph was shown to represent the length of an optimal scalar linear solution of the corresponding instance of the Index Coding with Side Information (ICSI) problem. In this paper, the graphs and digraphs of near-extreme min-ranks are studied. Those graphs and digraphs correspond to the ICSI instances having near-extreme transmission rates when using optimal scalar linear index codes. In particular, it is shown that the decision problem whether a digraph has min-rank two is NP-complete. By contrast, the same question for graphs can be answered in polynomial time. In addition, a circuit-packing bound is revisited, and several families of digraphs, optimal with respect to this bound, whose min-ranks can be found in polynomial time, are presented.

Index Terms—Index coding, network coding, side information, broadcast.

I. INTRODUCTION

Building communication schemes which allow participants to communicate efficiently has always been a challenging yet intriguing problem for information theorists. Index Coding with Side Information (ICSI) ([1], [2]) is a communication scheme dealing with broadcast channels in which receivers have prior side information about the messages to be transmitted. By using coding and exploiting the knowledge about the side information, the sender may significantly reduce the number of required transmissions compared with the straightforward approach. As a consequence, the efficiency of communication over this type of broadcast channels could be dramatically improved. Apart from being a special case of the well-known (non-multicast) Network Coding problem ([3], [4]), the ICSI problem has also found various potential applications on its own, such as audio- and video-on-demand, daily newspaper delivery, data pushing, and opportunistic wireless networks ([1], [2], [5]–[8]).

In the work of Bar-Yossef et al. [5], the optimal transmission rate of scalar linear index codes for an ICSI instance was neatly characterized by the so-called min-rank of the side information digraph (i.e., directed graph, see Section II for definitions) corresponding to that instance. The concept of min-rank of a graph (i.e., undirected graph, see Section II for definitions) goes back to Haemers [9]. Min-rank serves as an upper bound for the celebrated Shannon capacity of a graph [10]. This upper bound, as pointed out by Haemers, although is usually not as good as the Lovász bound [11], is sometimes tighter and easier to compute. It was shown by Peeters [12] that computing the min-rank of a general graph (that is, the Min-Rank problem) is a hard task. More specifically, Peeters showed that deciding whether the min-rank of a graph is smaller than or equal to three is an NP-complete problem.

The work of Bar-Yossef et al. [5] has stimulated the interest in the Min-Rank problem. Exact and heuristic algorithms for finding min-ranks over the binary field of digraphs were developed in the work of Chaudhry and Sprintson [13]. The min-ranks of random digraphs were investigated by Haviv and Langberg [14]. A dynamic programming approach was proposed by Berliner and Langberg [15] to compute min-ranks of outerplanar graphs in polynomial time. Algorithms to approximate min-ranks of graphs with bounded min-ranks were studied by Chlamtac and Haviv [16].

In this paper, we study graphs and digraphs that have near-extreme min-ranks. In other words, we study ICSI instances with n receivers for which optimal scalar linear index codes have transmission rates 1, 2, n−2, n−1, or n. In particular, we
show that deciding whether a digraph has min-rank two over the binary field is an NP-complete problem. Very recently, it was found by Maleki et al. [17] that the same problem for digraphs over sufficiently large field can be solved in polynomial time. By contrast, a graph has min-rank two over any finite field if and only if it is not a complete graph and its complement is bipartite, a condition which can be verified in polynomial time (see, for instance, West [18, p. 495]).

The characterizations of graphs and digraphs with near-extreme min-ranks are summarized in Table I. The star mark "★" indicates that the result is proved only for simple graphs, whereas the dagger mark "†" indicates that the result is proved only for the binary field.

The near-extreme cases are of significant interest from both theoretical and practical points of view. On the theoretical side, it is desirable to understand, which values of the min-rank are easy to verify in polynomial time (see, for instance, West [18, p. 495]).

For succinctness, we only study min-ranks of digraphs over a finite field \( \mathbb{F}_q \). However, all of our results, except Theorem 4.7, Corollary 4.8, and Theorem 5.2, still hold for an arbitrary field \( \mathbb{F} \). This is because the characteristic of the field does not play any role in their proofs.

The paper is organized as follows. Basic notation and definitions are presented in Section II. The ICSI problem is formulated in Section III. Section IV is devoted to the characterizations of graphs and digraphs of near-extreme min-ranks. We prove the hardness of the Min-Rank problem for digraphs in Section V. Families of digraphs that attain the circuit-packing bound [23] are discussed in Section VI. We conclude the paper in Section VII.

II. NOTATION AND DEFINITIONS

Let \([n]\) denote the set of integers \(\{1, 2, \ldots, n\}\). Let \(\mathbb{F}_q\) denote the finite field of \(q\) elements and \(\mathbb{F}_q^* = \mathbb{F}_q \setminus \{0\}\). The support of a vector \(u \in \mathbb{F}_q^n\) is defined to be the set \(\text{supp}(u) = \{i \in [n] : u_i \neq 0\}\). For an \(n \times k\) matrix \(M\), let \(M_i\) denote the \(i\)th row of \(M\). For a set \(E \subseteq [n]\), let \(M_{E}\) denote the \(|E| \times k\) sub-matrix of \(M\) formed by rows of \(M\) which are indexed by the elements of \(E\). For any matrix \(M\) over \(\mathbb{F}_q\), we denote by \(\text{rank}_q(M)\) the rank of \(M\) over \(\mathbb{F}_q\) (or the \(q\)-rank of \(M\)). We use \(e_i\) to denote the unit vector, which has a one at the \(i\)th position, and zeros elsewhere.

A simple graph is a pair \(G = (\mathcal{V}(G), \mathcal{E}(G))\) where \(\mathcal{V}(G)\) is the set of vertices of \(G\) and \(\mathcal{E}(G)\) is a set of unordered pairs of distinct vertices of \(G\). We refer to \(\mathcal{E}(G)\) as the set of edges of \(G\).

A typical edge of a graph \(G\) is of the form \(\{u, v\}\) where \(u \in \mathcal{V}(G)\), \(v \in \mathcal{V}(G)\), and \(u \neq v\). If \(e = \{u, v\} \in \mathcal{E}(G)\) we say that \(u\) and \(v\) are adjacent. We also refer to \(u\) and \(v\) as the endpoints of \(e\).

A simple digraph is a pair \(D = (\mathcal{V}(D), \mathcal{E}(D))\) where \(\mathcal{V}(D)\) is the set of vertices of \(D\), and \(\mathcal{E}(D)\) is a set of ordered pairs of distinct vertices of \(D\). We refer to \(\mathcal{E}(D)\) as the set of arcs (or directed edges) of \(D\). A typical arc of \(D\) is of the form \(e = (u, v)\) where \(u \in \mathcal{V}(D)\), \(v \in \mathcal{V}(D)\), and \(u \neq v\). The vertices \(u\) and \(v\) are called the endpoints of the arc \(e\).

Simple graphs and digraphs have no loops and no parallel edges and arcs, respectively. In the scope of this paper, only simple graphs and digraphs are considered. Therefore, we simply refer to them as graphs and digraphs for succinctness.

The number of vertices \(|\mathcal{V}(D)|\) is called the order of \(D\), whereas the number of arcs \(|\mathcal{E}(D)|\) is called the size of \(D\).

The complement of a digraph \(D\), denoted by \(\overline{D}\), is defined as follows. The vertex set is \(\mathcal{V}(\overline{D}) = \mathcal{V}(D)\). The arc set is \(\mathcal{E}(\overline{D}) = \{(u, v) : u, v \in \mathcal{V}(D), u \neq v, (u, v) \notin \mathcal{E}(D)\}\). Analogous concepts are also defined for graphs.

A digraph \(D\) is called symmetric if it satisfies the property that \((u, v) \in \mathcal{E}(D)\) if and only if \((v, u) \in \mathcal{E}(D)\). A symmetric digraph can be viewed as a graph, and vice versa. A complete graph is a graph that contains all possible edges. A complete digraph is a digraph that contains all possible arcs.

A collection of subsets \(V_1, V_2, \ldots, V_k\) of a set \(V\) is said to partition \(V\) if \(\bigcup_{i=1}^k V_i = V\) and \(V_i \cap V_j = \emptyset\) for every \(i \neq j\). In that case, \(V_1, V_2, \ldots, V_k\) is referred to as a partition of \(V\), and \(V_i\)'s \((i \in [k])\) are called parts of the partition.

A graph \(G\) is called bipartite if \(\mathcal{V}(G)\) can be partitioned into two subsets \(U\) and \(V\) such that for every edge \((u, v) \in \mathcal{E}(G)\), it holds that \(u \in U\) and \(v \in V\), or vice versa.

A subgraph of a graph \(G\) is a graph whose vertex set \(V\) is a subset of that of \(G\) and whose edge set is a subset of that of \(G\) restricted to the vertices in \(V\). Let \(V\) be a subset of vertices in \(\mathcal{V}(G)\). The subgraph of \(G\) induced by \(V\) is a graph whose vertex set is \(V\), and edge set is \(\{(u, v) : u \in V, v \in V, (u, v) \in \mathcal{E}(G)\}\). We refer to such a graph as an induced subgraph of \(G\). A subgraph and induced subgraph of a digraph can be defined in a similar manner.
A path in a graph $G$ is a sequence of distinct vertices $(v_1, v_2, \ldots, v_r)$, such that $(v_s, v_{s+1}) \in E(G)$ for all $s \in [r-1]$. A directed path in a digraph $D$ is a sequence of distinct vertices $(v_1, v_2, \ldots, v_r)$, such that $(v_s, v_{s+1}) \in E(D)$, for all $s \in [r-1]$.

A circuit in a digraph $D$ is a sequence of pairwise distinct vertices

$$C = (v_1, v_2, \ldots, v_r),$$

where $(v_s, v_{s+1}) \in E(D)$ for all $s \in [r-1]$ and $(v_r, v_1) \in E(D)$ as well. A digraph is called acyclic if it contains no circuits.

A graph is called connected if there is a path from each vertex in the graph to every other vertex. The connected components of a graph are its maximal connected subgraphs. Similarly, a digraph is called strongly connected if there is a directed path from each vertex in the graph to every other vertex. The strongly connected components of a digraph are its maximal strongly connected subgraphs.

If $(u, v)$ is an arc in a digraph $D$, then $v$ is called an out-neighbor of $u$ in $D$. The set of out-neighbors of a vertex $u$ in a digraph $D$ is denoted by $N^+(u)$. We simply use $N(u)$ whenever there is no potential confusion. We also denote by $N^-(u)$ the set of neighbors of $u$ in a graph $G$, namely, the set of vertices adjacent to $u$ in $G$.

An independent set in a graph $G$ is a set of vertices of $G$ with no edges connecting any two of them. An independent set in $G$ of largest cardinality is called a maximum independent set in $G$. The cardinality of such a maximum independent set is referred to as the independence number of $G$, denoted by $\alpha(G)$. We also use $\alpha(D)$ to denote the size of a maximum acyclic induced subgraph of a digraph $D$ for the following reason. For a symmetric digraph $D$, $\alpha(D)$ is equal to the size of a maximum independent set if $D$ is regarded as a graph.

A clique of a graph is a set of vertices that induces a complete subgraph of that graph. A clique cover of a graph is a set of cliques that partition its vertex set. A minimum clique cover of a graph is a clique cover with the minimum number of cliques. The number of cliques in such a minimum clique cover of a graph is called the clique cover number of that graph. Similar concepts are defined for digraphs. We denote by $cc(G)$ the clique cover number of a graph $G$ and $cc(D)$ the clique cover number of a digraph $D$.

### III. The Index Coding With Side Information Problem

The ICSI problem is formulated as follows. Suppose a sender $S$ wants to send a vector $x = (x_1, x_2, \ldots, x_n)$, where $x_i \in \Sigma^t$ for all $i \in [n]$, $\Sigma$ is some alphabet, to $n$ receivers $R_1, R_2, \ldots, R_n$. Each $R_i$ possesses some prior side information, consisting of the blocks $x_j$, $j \in \mathcal{X}_i \subseteq [n]$, and is interested in receiving a single block $x_i$. The sender $S$ broadcasts a codeword $C(x) \in \Sigma^k$, where $k$ is some positive integer, that enables each receiver $R_i$ to recover $x_i$ based on its side information. Such a mapping $C : \Sigma^m \rightarrow \Sigma^k$ is called an index code. We refer to $t$ as the block length and $k$ as the length of the index code. The ratio $k/t$ is called the transmission rate of the index code. The objective of $S$ is to find an optimal index code, that is, an index code which has the minimum transmission rate. The index code is called linear if $\Sigma = \mathbb{F}_q$ for some prime power $q$ and $E$ is a linear mapping. The index code is called scalar if $t = 1$ and block if $t > 1$. The length and the transmission rate of a scalar index code ($t = 1$) are identical.

Each instance of the ICSI problem can be described by the so-called side information digraph [5]. Given $n$ and $\mathcal{X}_i$, $i \in [n]$, the side information digraph $D = (\mathcal{V}(G), E(D))$ is defined as follows. The vertex set $\mathcal{V}(G) = \{u_1, u_2, \ldots, u_n\}$. The edge set $E(D) = \bigcup_{i \in [n]} \{(u_i, u_j) : j \in \mathcal{X}_i\}$. Sometimes we simply take $\mathcal{V}(D) = [n]$ and $E(D) = \bigcup_{i \in [n]} \{(i, j) : j \in \mathcal{X}_i\}$. If $D$ is a symmetric digraph, we can regard $D$ as a graph, and refer to $D$ as the side information graph.

**Definition 3.1 ([9])**: Let $D = (\mathcal{V}(D), E(D))$ be a digraph of order $n$, where $\mathcal{V}(D) = \{u_1, u_2, \ldots, u_n\}$.

1) A matrix $M = (m_{u_i, u_j}) \in \mathbb{F}_q^{n \times n}$ (whose rows and columns are labeled by the elements of $\mathcal{V}(D)$) is said to fit $D$ if

$$m_{u_i, u_j} \neq 0, \quad i = j,$$

$$m_{u_i, u_j} = 0, \quad i \neq j, \quad (u_i, u_j) \notin E(D).$$

2) The min-rank of $D$ over $\mathbb{F}_q$ is defined to be

$$\text{minrk}_q(D) \equiv \min \{\text{rank}_q(M) : M \in \mathbb{F}_q^{n \times n} \text{ and } M \text{ fits } D\}.$$
IV. DIGRAPHS OF NEAR-EXTREME MIN-RANKS

Some of the results presented below are folklore. However, we include them for the sake of completeness.

A. (Strongly) Connected Components and Min-Ranks

Lemma 4.1 (Folklore): Let $G = (V(G), E(G))$ be a graph. Suppose that $G_1, G_2, \ldots, G_k$ are subgraphs of $G$ that satisfy the following conditions:

1) The sets $V(G_i), i \in [k]$, partition $V(G)$;
2) There is no edge of the form $\{u, v\}$ where $u \in V(G_i)$ and $v \in V(G_j)$ for $i \neq j$.

Then

$$\minrk_q(G) = \sum_{i=1}^k \minrk_q(G_i).$$

In particular, the above equality holds if $G_1, G_2, \ldots, G_k$ are all connected components of $G$.

The proof follows from Definition 3.1.

Lemma 4.2 (Folklore): Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. If $D_1, D_2, \ldots, D_k$ are all strongly connected components of $D$, then

$$\minrk_q(D) = \sum_{i=1}^k \minrk_q(D_i).$$

The proof of this lemma appears in the Appendix.

These two lemmas suggest that it is sufficient to study the min-ranks of connected graphs and strongly connected digraphs, respectively.

B. Digraphs of Min-Rank One

The following results are known for (di-)graphs of min-rank one.

Proposition 4.3 (Folklore): Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. Then $\minrk_q(D) = 1$ if and only if $D$ is a complete digraph. The same statement holds for a graph.

Corollary 4.4 follows by applying Theorem 3.3 and Proposition 4.3.

Corollary 4.4: Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. Then $\beta(D) = 1$ if and only if $D$ is a complete digraph. The same statement holds for a graph.

C. Digraphs of Min-Rank Two

In this section, only the binary alphabet is considered. We first introduce the following concept of a fair coloring of a digraph. Recall that a $k$-coloring of a graph $G = (\mathcal{V}(G), \mathcal{E}(G))$ is a mapping $\phi: \mathcal{V}(G) \rightarrow [k]$ which satisfies the condition that $\phi(u) \neq \phi(v)$ whenever $\{u, v\} \in \mathcal{E}(G)$. We often refer to $\phi(u)$ as the color of $u$. If there exists a $k$-coloring of $G$, then we say that $G$ is $k$-colorable.

Definition 4.5: Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. A fair $k$-coloring of $D$ is a mapping $\phi: \mathcal{V}(D) \rightarrow [k]$ that satisfies the following conditions:

(C1) If $(u, v) \in \mathcal{E}(D)$ then $\phi(u) \neq \phi(v)$;
(C2) For each vertex $u$ of $D$, it holds that $\phi(v) = \phi(\omega)$ for all out-neighbors $v$ and $\omega$ of $u$.

If there exists a fair $k$-coloring of $D$, we say that we can color $D$ fairly by $k$ colors, or, $D$ is fairly $k$-colorable.

We refer to the condition (C2) as the fairness of the coloring, since this condition guarantees that all out-neighbors of each vertex share the same color.

Lemma 4.6: A digraph $D = (\mathcal{V}(D), \mathcal{E}(D))$ is fairly 3-colorable if and only if there exists a partition of $\mathcal{V}(D)$ into three subsets $A$, $B$, and $C$ that satisfy the following conditions:

1) For every $u \in A$: either $N_O(u) \subseteq B$ or $N_O(u) \subseteq C$;
2) For every $u \in B$: either $N_O(u) \subseteq A$ or $N_O(u) \subseteq C$;
3) For every $u \in C$: either $N_O(u) \subseteq A$ or $N_O(u) \subseteq B$.

Proof: If $D$ is fairly 3-colorable, let $A$, $B$, and $C$ respectively be the sets of vertices of $D$ that share the same color. Then clearly $A$, $B$, and $C$ partition $\mathcal{V}(D)$. Moreover, since all out-neighbors of each vertex must have the same color, the three conditions above are obviously satisfied. Conversely, if those conditions are satisfied, then $\phi: \mathcal{V}(D) \rightarrow [3]$, defined by

$$\phi(u) = \begin{cases} 1, & u \in A \\ 2, & u \in B \\ 3, & u \in C, \end{cases}$$

is a fair 3-coloring of $D$.

Theorem 4.7: Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. Then $\minrk_q(D) \leq 2$ if and only if $\overline{D}$, the complement of $D$, is fairly 3-colorable.

Proof:

The ONLY IF direction:

By the definition of min-rank, $\minrk_q(D) \leq 2$ implies the existence of an $n \times n$ binary matrix $M$ of 2-rank at most two that fits $D$. There must be some two rows of $M$ that span its entire row space. Without loss of generality, suppose that they are the first two rows of $M$, namely, $M_1$ and $M_2$ (these two rows might be linearly dependent if $\minrk_q(D) < 2$). Let $A$, $B$, and $C$ be disjoint subsets of $\mathcal{V}(D)$ such that

$$\supp(M_1) = A \cup B, \quad \supp(M_2) = B \cup C.$$

Hence,

$$\supp(M_1) \cap \supp(M_2) = B.$$

Since the binary alphabet is considered and the matrix $M$ has no zero rows, for every $u \in \mathcal{V}(D)$, one of the following must hold:

1) $M_u = M_1$;
2) $M_u = M_2$;
3) $M_u = M_1 + M_2$.

Hence for every $u \in \mathcal{V}(D)$

$$u \in \supp(M_u) \subseteq A \cup B \cup C.$$

This implies that $A \cup B \cup C = \mathcal{V}(D)$.

Suppose that $u \in A$. Then either $M_u = M_1$ or $M_u = M_1 + M_2$. The former condition holds if and only if $\supp(M_u) = A \cup B$, which in turns implies that $(u, v) \in \mathcal{E}(D)$ for all $v \in A \cup B \setminus \{u\}$. In other words, $(u, v) \notin \overline{\mathcal{E}(D)}$ for all $v \in A \cup B$. Hence $\overline{D} = (\mathcal{V}(\overline{D}), \mathcal{E}(\overline{D}))$ is the complement of $D$.

The latter condition holds if and only if $\supp(M_u) = A \cup C$, which implies that $(u, v) \notin \overline{\mathcal{E}(D)}$ for all $v \in A \cup C$. In summary, for every $u \in A$ we have
1) \((u, v) \notin E(D)_i\) for all \(v \in A\);
2) Either \((u, v) \notin E(D)\) for all \(v \in B\), or \((u, v) \notin E(D)\) for all \(v \in C\);

In other words, for every \(u \in A\), either \(N^O_D(u) \subseteq B\) or \(N^O_D(u) \subseteq C\). Analogous conditions hold for every \(u \in B\) and for every \(u \in C\) as well. Therefore, by Lemma 4.6, \(D\) is fairly 3-colorable.

**The IF direction:** Suppose now that \(D\) is fairly 3-colorable. It suffices to find an \(n \times n\) binary matrix \(M\) of rank at most two that fits \(D\). By Lemma 4.6, there exists a partition of \(V(D)\) into three subsets \(A, B,\) and \(C\) that satisfy the following three conditions

1) For every \(u \in A\): either \(N^O_D(u) \subseteq B\) or \(N^O_D(u) \subseteq C\);
2) For every \(u \in B\): either \(N^O_D(u) \subseteq A\) or \(N^O_D(u) \subseteq C\);
3) For every \(u \in C\): either \(N^O_D(u) \subseteq A\) or \(N^O_D(u) \subseteq B\).

We construct an \(n \times n\) matrix \(M = (m_{u,v})\) as follows. For each \(u \in A\), if \(N^O_D(u) \subseteq B\) then let

\[m_{u,v} = \begin{cases} 1, & v \in A \cup C \\ 0, & v \in B. \end{cases}\]

Otherwise, if \(N^O_D(u) \subseteq C\) then let

\[m_{u,v} = \begin{cases} 1, & v \in A \cup B \\ 0, & v \in C. \end{cases}\]

For \(u \in B\) and \(u \in C\), \(M_{u,v}\) can be constructed analogously. It is obvious that \(M\) fits \(D\). Moreover, each row of \(M\) can always be written as a linear combination of the two binary vectors whose supports are \(A \cup B\) and \(B \cup C\), respectively. Therefore, \(\text{rank}_2(M) \leq 2\). The proof is complete.

The following corollary characterizes the digraphs of min-rank two over \(\mathbb{F}_2\).

**Corollary 4.8:** A digraph \(D\) has min-rank two over \(\mathbb{F}_2\) if and only if \(D\) is fairly 3-colorable and \(D\) is not a complete digraph.

For a graph \(G\), it was proved by Blasiak et al. [26] that \(\beta(G) = 2\) if and only if \(\overrightarrow{G}\) is bipartite and \(G\) is not a complete graph. A characterization of digraphs \(D\) with \(\beta(D) = 2\) was also obtained therein. More specifically, it was shown that \(\beta(D) = 2\) if and only if \(D\) does not contain a subgraph isomorphic to an almost alternating cycle. The almost alternating \((2m + 1)\)-cycle \((m \geq 1)\) is defined as follows. Its vertex set consists of all integers between \(-m\) and \(m\), inclusive, and there is an edge from \(i\) to \(j\) if and only if \(j - i \in \{m, m + 1\}\).

Based on this characterization, a polynomial time algorithm to recognize a digraph \(D\) with \(\beta(D) = 2\) was also derived in [26]. Hence, the question whether an optimal block index code of length \(2\) exists for an ICSI instance described by a digraph can be answered in polynomial time. For scalar linear index codes, the same question turns out to be hard. We prove later in Section V that the decision problem whether \(\text{minrk}_2(D) = 2\) is NP-complete.

**D. Digraphs of Min-Ranks Equal to Their Orders**

We start with the following definition.

**Definition 4.9:** A matching in a graph is a set of edges without common vertices. A maximum matching is a matching that contains the largest possible number of edges. The number of edges in a maximum matching in \(G\) is denoted by \(\text{mm}(G)\).

**Proposition 4.10 (Maximum-matching bound):** For any graph \(G\) of order \(n\), it holds that \(\text{minrk}_2(G) \leq n - \text{mm}(G)\).

The proof follows from the clique-covering bound.

**Proposition 4.11 (Folklore):** Let \(G\) be a graph of order \(n\). Then \(\text{minrk}_q(G) = n\) if and only if \(G\) has no edges.

**Proposition 4.12 (Follows from [19]):** Let \(D\) be a digraph of order \(n\). Then \(\text{minrk}_q(D) = n\) if and only if \(D\) is acyclic.

It follows from Proposition 4.12 that the decision problem whether a digraph has min-rank equal to its order can be solved in polynomial time.

By Theorem 3.3, Proposition 4.11, and Proposition 4.12, the following corollary is straightforward.

**Corollary 4.13:** For a digraph \(D\), \(\beta(D) = |V(D)|\) if and only if \(D\) is acyclic. For a graph \(G\), \(\beta(G) = |V(G)|\) if and only if \(G\) has no edges.

**E. Graphs of Min-Ranks One Less Than Their Orders**

In this section, we consider (undirected) graphs. The corresponding case for digraphs is open. For a connected graph \(G\) of order at least two, it is easy to see that \(\text{mm}(G) = 1\) if and only if it is a star graph (for an example, see Fig. 2), which is defined as follows.

**Definition 4.14:** A graph \(G = (\{u, v\}, E(G))\) is called a star graph if \(|V(G)| \geq 2\) and there exists a vertex \(v \in V(G)\) such that \(E(G) = \{\{u, v\} : u \in V(G) \setminus \{v\}\}\).

It is straightforward to see that if \(\text{mm}(G) = 1\) then \(\alpha(G) = n - 1\), as \(G\) is a star graph.

**Proposition 4.15.** Let \(G\) be a connected graph of order \(n \geq 2\). Then \(\text{minrk}_q(G) = n - 1\) if and only if \(\text{mm}(G) = 1\) (or equivalently, \(G\) is a star graph).

**Proof:** We first suppose that \(\text{minrk}_q(G) = n - 1\). By the maximum-matching bound, \(n - 1 = \text{minrk}_q(G) \leq n - \text{mm}(G)\). Therefore, \(\text{mm}(G) \leq 1\). However, as \(\text{minrk}_q(G) = n - 1\), by Proposition 4.11 we have \(\text{mm}(G) \neq 0\). Hence, \(\text{mm}(G) = 1\).

Conversely, assume that \(\text{mm}(G) = 1\). By the maximum-matching bound, \(\text{minrk}_q(G) \leq n - 1\). By Proposition 3.4, \(\text{minrk}_q(G) \geq \alpha(G) = n - 1\). Thus, \(\text{minrk}_q(G) = n - 1\).

**Corollary 4.16:** Let \(G\) be a connected graph of order \(n \geq 2\). Then \(\beta(G) = n - 1\) if and only if \(\text{mm}(G) = 1\) (\(G\) is a star graph).

**Proof:** Suppose \(\beta(G) = n - 1\). Then either \(\text{minrk}_2(G) = n - 1\) or \(\text{minrk}_2(G) = n\). However, by Proposition 4.11, \(\text{minrk}_2(G) = n\) implies that \(G\) has no edge. As a consequence, \(\beta(G) \geq \alpha(G) = n\), which contradicts our assumption. Hence, \(\text{minrk}_2(G) = n - 1\). According to Proposition 4.15, \(\text{mm}(G) = 1\).
Suppose that $\alpha(G) = 1$. According to Proposition 4.15, we have

$$n - 1 = \alpha(G) \leq \beta(G) \leq \text{minrk}_2(G) = n - 1.$$ 

Hence, $\beta(G) = n - 1$.

### 2. Graphs of Min-Ranks Two Less Than Their Orders

In this section, we consider (undirected) graphs. The corresponding case for digraphs is open. Here we also employ the matching language to characterize graphs of min-ranks two less than their orders.

**Theorem 4.17.** Suppose $G$ is a connected graph of order $n \geq 6$. Then $\text{minrk}_r(G) = n - 2$ if and only if $\text{mm}(G) = 2$ and $G$ does not contain a subgraph isomorphic to the graph $\mathfrak{F}$ depicted in Fig. 1.

The proof of this theorem appears in the Appendix.

**Corollary 4.18.** If $\text{mm}(G) = 2$ and $G$ contains a subgraph isomorphic to $\mathfrak{F}$ (Fig. 3) then $\text{minrk}_2(G) = |V(G)| - 3$.

**Proof:** Suppose $\mathfrak{F}'$ (Fig. 3) is a subgraph of $G$ that is isomorphic to $\mathfrak{F}$.

As $G$ does not have a matching of size three, each of the vertices $c, f,$ and $g$ is not adjacent to any vertex in $V(G) \setminus V(\mathfrak{F}')$. Moreover, no pairs of vertices in $V(G) \setminus V(\mathfrak{F}')$ are adjacent for the same reason. Therefore, $(c, f, g) \cup (V(G) \setminus V(\mathfrak{F}'))$ is an independent set of size $|V(G)| - 3$ in $G$. Hence, $\text{minrk}_2(G) \geq \alpha(G) \geq |V(G)| - 3$.

Theorem 4.17 holds verbatim if we replace $\text{minrk}_2(-)$ by $\beta(-)$.

**Proof:** Suppose that $\beta(G) = n - 2$. Then $\text{minrk}_2(G) \in \{n - 2, n - 1, n\}$. By Proposition 4.11, Proposition 4.15, and their corollaries, for $\kappa \in \{n - 1, n\}$, $\text{minrk}_2(G) = \kappa$ if and only if $\beta(G) = \kappa$. Therefore, $\text{minrk}_2(G) = n - 2$. According to Theorem 4.17, $\text{mm}(G) = 2$ and $G$ does not contain a subgraph isomorphic to $\mathfrak{F}$.

Conversely, as shown in the proof of Theorem 4.17 (the IF direction), $\alpha(G) = \text{minrk}_2(G) = n - 2$. Therefore, $\beta(G) = n - 2$ by Theorem 3.3.

### V. The Hardness of the Min-Rank Problem for Digraphs

In this section, we first prove that it is an NP-complete problem to decide whether a given digraph is fairly $k$-colorable (see Definition 4.5), for any given integer $k \geq 3$. The hardness of this problem, by Lemma 4.3 and Corollary 4.8, leads to the hardness of the decision problem whether a given digraph has min-rank two over $\mathbb{F}_2$. The fair $k$-coloring problem is defined formally as follows.

**Problem: FAIR $k$-COLORING**

**Input:** A digraph $D$, an integer $k$

**Output:** True if $D$ is fairly $k$-colorable, False otherwise

**Theorem 5.1.** The fair $k$-coloring problem is NP-complete for $k \geq 3$.

**Proof:** This problem is obviously in NP, as the algorithm can guess a candidate for the fair coloring and verify that the candidate is indeed a fair coloring in polynomial time. For NP-hardness, we reduce the $k$-coloring problem to the fair $k$-coloring problem. Recall that the $k$-coloring problem is the decision problem whether a given graph is $k$-colorable. Suppose that $G = (V(G), E(G))$ is an arbitrary graph. We aim to build a digraph $D = (V(D), E(D))$ so that $G$ is $k$-colorable if and only if $D$ is fairly $k$-colorable. Suppose that $V(G) = [n]$. For each vertex $i \in [n]$, we build the following gadget, which is a digraph $D_i = (V_i, E_i)$. The vertex set of $D_i$ is

$$V_i = \{i\} \cup \{\omega_{i,j} : j \in N^G(i)\},$$

where $\omega_{i,j}$ are newly introduced vertices. We refer to $\omega_{i,j}$ as a clone (in $D_i$) of the vertex $j \in [n]$. The arc set of $D_i$ is

$$E_i = \{(\omega_{i,j}, i) : j \in N^G(i)\}.$$ Let $N^G(i) = \{i, i_1, \ldots, i_n\}$. Then $D_i$ can be drawn as in Fig. 4.

Additionally, we also introduce $n$ new vertices $p_1, p_2, \ldots, p_n$. The digraph $D = (V(D), E(D))$ is built as follows. The vertex set of $D$ is

$$V(D) = \left( \bigcup_{i=1}^n V_i \right) \cup \{p_1, p_2, \ldots, p_n\}.$$ Let

$$Q_i = \{(p_i, i)\} \cup \{(p_i, \omega_{i',i}) : i' \in [n], i \in N^G(i')\}$$

be the set consisting of $(p_i, i)$ and the arcs that connect $p_i$ and all the clones $\omega_{i',i}$ of $i$. The arc set of $D$ is then defined to be

$$E(D) = \left( \bigcup_{i=1}^n E_i \right) \cup \left( \bigcup_{i=1}^n Q_i \right).$$

For example, if $G$ is the graph in Fig. 5, then $D$ is the digraph in Fig. 6.
Fig. 6. The digraph $D$ built from the graph $G$ in Fig. 5.

Our goal now is to show that $G$ is $k$-colorable if and only if $D$ is fairly $k$-colorable.

Suppose that $G$ is $k$-colorable and $\phi_{G} : [n] \to [k]$ is a $k$-coloring of $G$. We consider the mapping $\phi_{D} : V(D) \to [k]$ defined as follows

1) For every $i \in [n]$, $\phi_{D}(i) = \phi_{G}(i)$;
2) If $i \in N^{G}(i')$ then $\phi_{D}(\omega_{i,i'}) = \phi_{D}(i) = \phi_{G}(i)$, in other words, clones of $i$ have the same color as $i$;
3) For every $i \in [n]$, $\phi_{D}(p_{i})$ can be chosen arbitrarily, as long as it is different from $\phi_{D}(i)$.

We claim that $\phi_{D}$ is a fair $k$-coloring for $D$. We first verify the condition (C1) (see Definition 4.5). It is straightforward from the definition of $\phi_{D}$ that the endpoints of each of the arcs of the forms $(p_{i},i)$ for $i \in [n]$, and $(p_{i},\omega_{i,i})$ for $i \in N^{G}(i')$, have different colors. It remains to check if $i$ and $\omega_{i,j}$ for $j \in N^{G}(i)$ have different colors. On the one hand, $\omega_{i,j}$ is a clone of $j$, and hence it has the same color as $j$. In other words,

$\phi_{D}(\omega_{i,j}) = \phi_{D}(j) = \phi_{G}(j)$.

On the other hand, since $j \in N^{G}(i)$, we obtain that

$\phi_{G}(j) \neq \phi_{G}(i) = \phi_{D}(i)$.

Therefore, $\phi_{D}(\omega_{i,j}) \neq \phi_{D}(i)$ for all $i \in [n]$ and $j \in N^{G}(i)$. Thus, (C1) is satisfied.

We now check if (C2) (see Definition 4.5) is also satisfied. The out-neighbors of $p_{i}$ are $i$ and its clones $\omega_{i,i'} (i \in N^{G}(i'))$. These vertices have the same color in $D$, namely $\phi_{D}(i)$, by the definition of $\phi_{D}$. Thus (C2) is also satisfied. Therefore $\phi_{D}$ is a fair $k$-coloring of $D$.

Conversely, suppose that $\phi_{D} : V(D) \to [k]$ is a fair $k$-coloring of $D$. Condition (C2) guarantees that all clones of $i$ have the same color as $i$, namely, $\phi_{D}(\omega_{i,i'}) = \phi_{D}(i)$ if $i \in N^{G}(i')$. Therefore, by (C1), if $\{i,j\} \in E(G)$, that is, $j \in N^{G}(i)$, then $\phi_{D}(i) \neq \phi_{D}(\omega_{i,j}) = \phi_{D}(j)$.

Hence, if we define $\phi_{G} : [n] \to [k]$ by $\phi_{G}(i) = \phi_{D}(i)$ for all $i \in [n]$, then it is a $k$-coloring of $G$. Thus $G$ is $k$-colorable.

Finally, notice that the order of $D$ is a polynomial with respect to the order of $G$. More specifically, $|V(D)| = 2|V(G)| + 2|E(G)|$ and $|E(D)| = |V(G)| + 4|E(G)|$. Moreover, building $D$ from $G$, and also obtaining a coloring of $G$ from a coloring of $D$, can be done in polynomial time with respect to the order of $G$. Since the $k$-coloring problem ($k \geq 3$) is NP-hard [28], we conclude that the fair $k$-coloring problem is also NP-hard.

According to Theorem 5.1 and the work by Blasiak et al. [26] (see the discussion after Corollary 4.8), we obtain the following.

Theorem 5.2. Let $D$ be an arbitrary digraph. Then the decision problem whether $\minrk_{q}(D) = 2$ is NP-complete. However, the decision problem whether $\beta(D) = 2$ can be solved in polynomial time.

Recall that by contrast, for a graph $G$, it was observed by Peeters [12] that $G$ has min-rank two if and only if $G$ is a bipartite graph and $G$ is not a complete graph, which can be verified in polynomial time (see, for instance, West [18, p. 495]). Note that a graph is bipartite if and only if it is 2-colorable. This fact can also be derived by applying Theorem 4.7 to the digraph obtained from $G$ by replacing each edge of $G$ by two arcs of opposite directions.

VI. CIRCUIT-PACKING BOUND REVISITED

In this section, we discuss a circuit-packing bound [23] for the min-rank of a digraph. We investigate families of digraphs, whose min-ranks attain the bound and are computable in polynomial time.

A. The Bound

Let $v_{0}(D)$ be the circuit-packing number of $D$, namely, the maximum number of vertex-disjoint circuits in $D$. Below, we reproduce an upper bound on min-ranks of digraphs, which uses the circuit packing number. This bound was first presented by Chaudhry et al. in [23].

Proposition 6.1 (Circuit-packing bound, [23]): The following holds for every digraph $D$ of order $n$:

$$\minrk_{q}(D) \leq n - v_{0}(D).$$

Whereas for graphs the clique-cover bound is the best known bound, for digraphs that are not symmetric, this is not the case. The worst scenario for the clique-cover bound is when the digraph has no two arcs of opposite directions. For such a digraph, this bound becomes trivial, as the size of the smallest clique cover is equal to the order of the digraph. The following example emphasizes the fact that for certain digraphs, the circuit-packing bound can be significantly tighter than the clique-cover bound.

Example 6.2. Let $D$ be the digraph of order $n = 3k$ depicted in Fig. 7. As there are no arcs of opposite directions, all cliques in $D$ are of cardinality one. Therefore, the clique-cover bound gives $\minrk_{q}(D) \leq 3k$. On the other hand, as $D$ contains $k$ vertex-disjoint circuits, namely $C_{1} = (3i + 1, 3i + 2, 3i + 3)$ for $i = 0, 1, \ldots, k - 1$, the circuit-packing bound yields $\minrk_{q}(D) \leq 2k = 3k - k$. The gap between the two bounds is one third of the order of the digraph.

B. Digraphs Attaining Circuit-Packing Bound

In this subsection, we present several new examples of families of digraphs that attain the circuit-packing bound.
A feedback vertex (arc, respectively) set of $D$ is a set of vertices (arcs, respectively) whose removal destroys all circuits in $D$. Let $\tau_0(D)$ ($\tau_1(D)$, respectively) denote the minimum size of a feedback vertex (arc, respectively) set of $D$. Then it is clear that $\alpha(D) = n - \tau_0(D)$.

**Corollary 6.3.** If $\nu_0(D) = \tau_0(D)$ then

$$\min rk_\nu(D) = n - \nu_0(D) = n - \tau_0(D).$$

**Proof:** By Proposition 3.4 and Proposition 6.1 we have $n - \tau_0(D) \leq \min rk_\nu(D) \leq n - \nu_0(D)$.

Hence, the proof follows.

When $D$ satisfies $\nu_0(D) = \tau_0(D)$, we say that $D$ satisfies the min-max vertex equality. In that case, the circuit-packing bound is tight. Similarly, let $\nu_1(D)$ denote the maximum number of arc-disjoint circuits in $D$. We say that $D$ satisfies the min-max arc equality if $\nu_1(D) = \tau_1(D)$.

An example of digraphs that satisfy the min-max vertex equality is the connectively reducible digraphs [29]. This family of digraphs contains both the family of fully reducible flow digraphs [30] and the family of cyclically reducible digraphs [31] as special cases. A polynomial time algorithm was provided by Szwarcfiter [29] to recognize a member of this family and subsequently find a maximum set of vertex-disjoint circuits as well as a minimum feedback vertex set. Therefore, by Corollary 6.3, (1) holds for a connectively reducible digraph $D$. Moreover, $\min rk_\nu(D)$ can be found in polynomial time.

Another example of digraphs for which the circuit-packing bound is tight are the digraphs that pack [32]. A digraph packs if the min-max vertex equality holds for all of its subgraphs. The digraphs in this family are exactly those that have no minor isomorphic to an odd double circuit or $F_7$, a special digraph of order 7 (interested readers may refer to [32] for more details, also for a structural characterization of this family of digraphs). For instance, strongly planar digraphs [32] belong to this family. As far as we know, there are no known polynomial time algorithms to find a minimum feedback vertex set of a digraph that packs.

Other examples of digraphs for which the circuit-packing bound is tight are the line digraphs of planar digraphs, of fully reducible flow digraphs, and of (special) Eulerian digraphs [33].

**Definition 6.4.** Let $D = (\mathcal{V}(D), \mathcal{E}(D))$ be a digraph. Then the digraph $\mathcal{L} = (\mathcal{V}(\mathcal{L}), \mathcal{E}(\mathcal{L}))$ with $\mathcal{V}(\mathcal{L}) = \mathcal{E}(D)$ and

$$\mathcal{E}(\mathcal{L}) = \{ (e, e') : e = (u, v) \in \mathcal{E}(D), e' = (v, w) \in \mathcal{E}(D) \},$$

is called the line digraph of $D$. We denote the line digraph of $D$ by $\mathcal{L}(D)$. The digraph $\mathcal{L}(D)$ is called a root digraph of $\mathcal{L}(D)$.

**Lemma 6.5.** $\nu_0(\mathcal{L}(D)) = \nu_1(D)$.

The proof of this lemma appears in the Appendix.

**Lemma 6.6.** $\tau_0(\mathcal{L}(D)) = \tau_1(D)$.

The proof of this lemma appears in the Appendix.

**Proposition 6.7.** Let $D$ be a digraph. If $\nu_1(D) = \tau_1(D)$ then $\nu_0(\mathcal{L}(D)) = \tau_0(\mathcal{L}(D))$ and

$$\min rk_\nu(\mathcal{L}(D)) = |\mathcal{E}(D)| - \nu_1(D).$$

**Proof:** Suppose that $\nu_1(D) = \tau_1(D)$. By Lemma 6.5 and Lemma 6.6, $\nu_0(\mathcal{L}(D)) = \tau_0(\mathcal{L}(D))$. Therefore, by applying Corollary 6.3 to $\mathcal{L}(D)$ we obtain

$$\min rk_\nu(\mathcal{L}(D)) = |\mathcal{V}(\mathcal{L}(D))| - \nu_0(\mathcal{L}(D)) = |\mathcal{E}(D)| - \nu_1(D).$$

**Definition 6.8.** A digraph that can be drawn on a plane in such a way that its (arc) edges intersect only at their endpoints is called planar.

It is known that the min-max arc equality is satisfied for planar digraphs [34], for fully reducible flow digraphs [35], and for a special family of Eulerian digraphs [33]. Therefore, by Proposition 6.7, the min-max vertex equality is satisfied for the line digraphs of the members of these families. In summary, we have the following.

**Corollary 6.9.** The circuit-packing bound is tight for the following families of digraphs: connectively reducible digraphs, digraphs that pack, line digraphs of planar digraphs, line digraphs of fully reducible flow digraphs, and line digraphs of special Eulerian digraphs.

Consider the ICSI instances described by digraphs $D$ with $\min rk_\nu(D) = \alpha(D)$. By Theorem 3.3, $\min rk_\nu(D) = \beta(D)$. Hence, for such instances, scalar linear index codes are as good as block index codes, in terms of transmission rates. Thus, for the ICSI instances described by families of digraphs listed in Corollary 6.9, scalar linear index codes achieve the best possible transmission rates. Previously, only perfect graphs and acyclic digraphs were known to have this property [19].

**Definition 6.10.** A digraph is called partially planar if all of its strongly connected components are planar.

**Proposition 6.11.** There is a polynomial time algorithm to recognize the line digraph of a partially planar digraph and subsequently determine its min-rank.

**Proof:** We present an algorithm as claimed. It consists of two phases.

1. **Recognition Phase:** To determine whether a given digraph $\mathcal{L}$ is the line digraph of a partially planar digraph, it suffices to determine whether each of its strongly connected components $\mathcal{L}_i$ ($i \in [k]$) is the line digraph of a planar digraph. All strongly connected digraphs of planar digraphs have been recognized by the algorithm of Szwarcfiter [29]. Therefore, the recognition task can be achieved in $O(n^2)$ time.

2. **Min-Rank Phase:** To compute $\min rk_\nu(\mathcal{L}(D))$, we need to determine $\nu_0(\mathcal{L}(D))$ and $\nu_1(D)$.

Fig. 7. Example where the circuit-packing bound is tighter than the clique-cover bound.
components of a digraph can be found in time linear in the number of edges [36].
For each \(i \in [k]\), we can efficiently determine whether \(\mathcal{L}_i\) is a line digraph of a digraph [37]. If yes, the algorithm outputs a digraph \(D'_i\), which is a root digraph of \(\mathcal{L}_i\) and is strongly connected.
Suppose \(\mathcal{L} = \mathcal{L}(D)\), where \(D\) is a digraph. Let \(\mathcal{L}_i = \mathcal{L}(D'_i)\), where \(D'_i\)'s, \(i \in [k]\), are all strongly connected components of \(D\) of order \(\geq 2\). By [38, Theorem 3], \(D'_i\) and \(D_i\) are isomorphic, \(i \in [k]\). To complete the Recognition Phase, one tests the planarity of \(D_i\) for every \(i \in [k]\). This can be done in time linear in the size of \(D\) [39].

2) \textbf{Min-Rank Computation Phase:}\ If \(\mathcal{L}\) is the line digraph of a partially planar digraph, then \(\minrk_q(\mathcal{L})\) can be computed efficiently. Indeed, by Lemma 4.2, it suffices to show that \(\minrk_q(\mathcal{L}_i)\) for \(i \in [k]\) can be found in polynomial time.
Since \(D'_i\) (which is isomorphic to \(D_i\)) is planar, as it is shown in [34], \(\nu_1(D'_i) = \tau_1(D_i)\). Therefore, by Proposition 6.7,
\[
\minrk_q(\mathcal{L}_i) = |\mathcal{E}(D'_i)| - \nu_1(D'_i),
\]
where \(\nu_1(D'_i)\) can be computed efficiently (40).
Therefore, \(\minrk_q(\mathcal{L})\) can be computed efficiently. \(\blacksquare\)

In summary, we have the following result.

**Corollary 6.12.** There are polynomial time algorithms to recognize a member and subsequently determine the min-rank of that member of the following families of digraphs: connectively reducible digraphs (which includes fully reducible flow digraphs and cyclically reducible digraphs), and line digraphs of partially planar digraphs.

**VII. CONCLUSION**
We studied the ICSI instances whose optimal scalar linear index codes have near-extreme transmission rates. We presented new characterizations of side-information graphs with min-ranks \(n - 1\) and \(n - 2\) over a general finite field, and of digraphs with min-rank two over the binary field. We also showed that the decision problem whether a digraph has min-rank two (over a general finite field) is NP-complete. Finally, we presented several families of digraphs, whose min-ranks can be found efficiently.

**APPENDIX**

**Proof of Lemma 4.2:** Suppose that \(\mathcal{V}_i\) is the set of vertices that induces \(D_i\), \(i \in [k]\). Then \(\{\mathcal{V}_i\}_{i \in [k]}\) forms a partition of \(\mathcal{V}(D)\). By relabeling the vertices of \(D\) if necessary, we may assume without loss of generality that for every \(i < j\)
1. \(u < v\) whenever \(u \in \mathcal{V}_i\) and \(v \in \mathcal{V}_j\);
2. There are no arcs of the form \((v, u)\) where \(u \in \mathcal{V}_i\) and \(v \in \mathcal{V}_j\).
If \(M^{(i)}\) is a minimum-rank matrix that fits \(D_i\) (\(i \in [k]\)) then the diagonal block matrix \(M\) whose diagonal blocks are \(M^{(i)}\) clearly fits \(D\). Moreover,
\[
\rank_q(M) = \sum_{i=1}^{k} \rank_q(M^{(i)}) = \sum_{i=1}^{k} \minrk_q(D_i).
\]

Hence \(\minrk_q(D) \leq \sum_{i=1}^{k} \minrk_q(D_i)\). It remains to show that \(\minrk_q(D) \geq \sum_{i=1}^{k} \minrk_q(D_i)\). Suppose that the matrix \(M\) fits \(D\). By the assumptions on \(\mathcal{V}_i\)'s (\(i \in [k]\)) stated at the beginning of the proof, \(M\) must be an upper-triangular block matrix. If we let \(M^{(i)}\) be the sub-matrix of \(M\) formed by the rows and columns indexed by the elements of \(\mathcal{V}_i\), then \(M^{(i)}\) fits \(D_i\) and hence,
\[
\rank_q(M) \geq \sum_{i=1}^{k} \rank_q(M^{(i)}) \geq \sum_{i=1}^{k} \minrk_q(D_i).
\]
Thus, \(\minrk_q(D) \geq \sum_{i=1}^{k} \minrk_q(D_i)\).

**Proof of Theorem 4.17:** For the ONLY IF direction, suppose that \(\minrk_q(G) = n - 2\). By the maximum-matching bound, \(n - 2 \leq n - \mm(G)\). Hence \(\mm(G) \leq 2\). As \(\mm(G) \in \{0, 1\}\) and \(\nu(G) \geq 6\) imply that either \(G\) has no edges (\(\mm(G) = n \geq n - 2\)) or \(G\) is a star graph (\(\mm(G) = n - 1 > n - 2\)), we deduce that \(\mm(G) = 2\). Moreover, as the graph \(\mathcal{G}\) has min-rank three less than its order, \(G\) should not contain any subgraph isomorphic to \(\mathcal{G}\). Indeed, suppose for otherwise that \(\mathcal{G}'\) is a subgraph of \(G\) and \(\mathcal{G}'\) is isomorphic to \(\mathcal{G}\).

Consider the following block diagonal matrix \(M\) with two blocks \(B_1\) and \(B_2\). The first block \(B_1\), a \(6 \times 6\) matrix, corresponds to the rows and columns labeled by the vertices in \(\mathcal{G}'\). Moreover, we choose \(B_2\) so that it has \(q\)-rank three. This is possible since \(\mathcal{G}'\) is isomorphic to \(\mathcal{G}\) and \(\minrk_q(\mathcal{G}) = 3\). (Note that \(3 = \alpha(\mathcal{G}) \leq \minrk_q(\mathcal{G}) \leq \alpha(\mathcal{G}) = 3\) implies that \(\minrk_q(\mathcal{G}) = 3\).) The second block \(B_2\) is chosen to be an \((n - 6) \times (n - 6)\) identity matrix. It corresponds to the rows and columns labeled by the vertices in \(\mathcal{V}(G) \setminus \mathcal{V}(\mathcal{G}')\). Then \(M\) fits \(G\) and moreover,
\[
\rank_q(M) = \rank_q(B_1) + \rank_q(B_2) = 3 + (n - 6) = n - 3.
\]
This implies that \(\minrk_q(G) \leq n - 3 < n - 2\), which is impossible.

We now turn to the IF direction. Suppose that \(\mm(G) = 2\) and \(G\) does not contain any subgraph isomorphic to \(\mathcal{G}\). Then by the maximum-matching bound, \(\minrk_q(G) \leq n - 2\). As \(\alpha(G) \leq \minrk_q(G)\), it suffices to show that \(\alpha(G) = n - 2\).

Let \(\{a, b\}\) and \(\{c, d\}\) be the two edges of a maximum matching \(M\) in \(G\). Let \(U = \{a, b, c, d\}\) and \(V = \mathcal{V}(G) \setminus U\). As \(G\) has at least six vertices, suppose that \(V = \{f, g, \ldots\}\), where \(f \neq g\). Since \(M\) is a maximum matching, \(V\) must be an independent set in \(\mathcal{G}\). The idea is to show that we can always find two nonadjacent vertices in \(U\) that are not adjacent to any vertex in \(V\). Such two vertices can be added to \(V\) to obtain an independent set of size \(n - 2\), which establishes the proof. We refer to such a pair of vertices as an \textit{independent pair}.

For disjoint subsets \(I\) and \(J\) of \(\mathcal{V}(G)\), let
\[
s_G(I, J) = |\{i, j\} : i \in I, j \in J, \{i, j\} \in \mathcal{E}(G)\}|
\]
Based on how the vertices in \(U\) are connected to each other, we consider the following five cases. Note that we only consider non-isomorphic configurations.
Without loss of generality, suppose any vertex in the one hand, since {ab}, {ac}, {ad}, {bc}, {bd}. All of these pairs fail to be an independent pair if and only if both a and b are adjacent to some vertices in V or both c and d are adjacent to some vertices in V. We show that either case never happens, by contradiction.

Suppose both a and b are adjacent to some vertices in V. (The case when both c and d are adjacent to some vertices in V is investigated analogously.) Without loss of generality, assume that a and f are adjacent. Then b must be adjacent to f but not to any other vertex in V. Indeed, if b is adjacent to h ∈ V, h ≠ f, then the set of three edges {a, f}, {b, h}, and {c, d} form a matching of size three, which is impossible since mm(G) = 2. Similarly, a should not be adjacent to any other vertex in V rather than f.

As G is connected, f must be adjacent to either c or d. Without loss of generality, suppose f and c are adjacent. On the one hand, since G is connected, g must be adjacent to some vertex in U. On the other hand, g cannot be adjacent to any vertex in U, as
- if g and a are adjacent, then {a, g}, {b, f}, and {c, d} form a matching of size three, which is impossible;
- if g and b are adjacent, then {a, f}, {b, g}, and {c, d} form a matching of size three, which is impossible;
- if g and c are adjacent, then G has a subgraph isomorphic to Fig. 8, which is impossible;
- if g and d are adjacent, then {a, b}, {c, f}, and {d, g} form a matching of size three, which is impossible.

We obtain a contradiction.

Case 2: s(G)({ab}, {cd}) = 1. Without loss of generality, suppose that {bc} is the only edge that connects {ab} and {cd}.

There are three candidates for an independent pair, namely {ac}, {ad}, and {bd}. All of these three pairs fail to be an independent pair only if at least one of the pairs {ab}, {ac}, and {bd} has both vertices adjacent to some vertices in V. We show below that this scenario cannot happen.

1) Assume that both a and b are adjacent to some vertices in V.
Suppose without loss of generality that a and f are adjacent. Then the same argument as in Case 1 establishes that b must be adjacent to f but not to any other vertex in V. On the one hand, as G is connected, g must be adjacent to some vertex in U. On the other hand, as mm(G) = 2, g should not be adjacent to any vertex among a, b, and d. Moreover, g and c cannot be adjacent, for otherwise G would contain a subgraph isomorphic to Fig. 9. We obtain a contradiction.

2) Assume that both a and d are adjacent to some vertices in V (Fig. 10). Suppose without loss of generality that a and f are adjacent. As there are no matchings of size three in G, d is adjacent to f but not to any other vertex in V. Also, g is not adjacent to any vertex in U. However, this would imply that g is an isolated vertex of G, which is impossible as G is connected.

3) Assume that both c and d are adjacent to some vertices in V. This sub-case is completely similar to the first sub-case.

Case 3: s(G)({ab}, {cd}) = 2 and the two edges that connect {ab} and {cd} share one common vertex. Without loss of generality suppose that these two edges are {ab} and {bd}.

There are two candidates for an independent pair, namely {ac} and {ad}. It suffices to show that a is not adjacent to any vertex in V and either c or d is not adjacent to any vertex in V.

Suppose that a is adjacent to a vertex, say f, in V. As mm(G) = 2, we deduce that g is not adjacent to any vertex among b, c, and d. Also, since G does not contain a subgraph isomorphic to Fig. 9, we deduce that g cannot be adjacent to a (see Fig. 11). Hence g is an isolated vertex of G, which is impossible as G is connected.

Now suppose that both c and d are adjacent to some vertices in V. Without loss of generality, suppose that c is adjacent to f. Then since mm(G) = 2, d must be adjacent to f but not to any other vertex in V. Also, g cannot be adjacent to any vertex among a, c, and d for the same reason. Moreover, as G does not contain a subgraph isomorphic to Fig. 9, we deduce...
that $g$ is not adjacent to $b$ (see Fig. 12). (Indeed, if $g$ and $b$ are adjacent, then the following subgraph of $G$ is isomorphic to $\mathcal{G}$: its vertex set is $\{a,b,c,d,f,g\}$, and its edge set is $\{(c,d),\{d,f\},\{c,f\},\{b,a\},\{b,g\}\}$. Therefore, $g$ is an isolated vertex of $G$. We obtain a contradiction.

**Case 4:** $s_G(\{a,b\},\{c,d\}) = 2$ and the two edges that connect $\{a,b\}$ and $\{c,d\}$ share no common vertices. Suppose, without loss of generality, that these two edges are $\{a,d\}$ and $\{b,c\}$ (Fig. 13).

There are two candidates for an independent pair, namely $\{a,c\}$ and $\{b,d\}$. Both of these pairs fail to be an independent pair if and only if at least one of the four pairs $\{a,b\},\{a,d\},\{b,c\}$, and $\{c,d\}$ has both vertices adjacent to some vertices in $V$. By symmetry, it suffices to show that the scenario when both $a$ and $b$ are adjacent to some vertices in $V$ never happens.

Suppose now that $a$ and $b$ are adjacent to some vertices in $V$.

Suppose that $a$ and $f$ are adjacent. The condition that $\text{mm}(G) = 2$ forces $b$ to be adjacent to $f$ but not to any other vertex in $V$. That condition also implies that $g$ must be an isolated vertex in $G$, which is impossible as $G$ is connected.

**Case 5:** $s_G(\{a,b\},\{c,d\}) = 3$. Without loss of generality, suppose that $\{a,b\},\{b,c\}$, and $\{b,d\}$ are the edges that connect $\{a,b\}$ and $\{c,d\}$. The only candidate for an independent pair is $\{a,c\}$. We prove by contradiction that both $a$ and $c$ are not adjacent to any vertex in $V$. By symmetry, it suffices to verify this property for only one of them.

Suppose that $a$ is adjacent to some vertex in $V$. Let $b$ be adjacent to $f$.

As $\text{mm}(G) = 2$ and $G$ is connected, $g$ must be adjacent to $a$. However, $G$ now contains a subgraph whose edge set consists of $\{b,c\},\{b,d\},\{c,d\},\{b,a\},\{a,f\},\{a,g\}$, which is isomorphic to $\mathcal{G}$ (see Fig. 14). This contradicts our assumption.

**Case 6:** $s_G(\{a,b\},\{c,d\}) = 4$. In this case, the subgraph of $G$ induced by $\{a,b,c,d\}$ is a complete graph (Fig. 15).

As $G$ is connected, both $f$ and $g$ must be adjacent to some vertices in $U$. If $f$ and $g$ are adjacent to the same vertex in $U$, then $G$ contains a subgraph isomorphic to $\mathcal{G}$, which contradicts our assumption. For instance, if both $f$ and $g$ are adjacent to $a$, then this subgraph has vertex set $\{a,b,c,d,f,g\}$ and edge set consisting of the edges $\{b,c\},\{c,d\},\{b,a\},\{a,f\},\{a,g\}$. It is also easy to verify that if $f$ and $g$ are adjacent to different vertices in $U$, then $G$ contains a matching of size three. This contradicts our assumption that $\text{mm}(G) = 2$. Thus, Case 6 never happens.

**Proof of Lemma 6.5:**

1) $\nu_0(\mathcal{L}(D)) \geq \nu_1(D)$. It suffices to show that the existence of a set of arc-disjoint circuits in $D$ implies the existence of a set of vertex-disjoint circuits of the same size in $\mathcal{L}(D)$. Let $\{C_1,C_2,\ldots,C_k\}$ be a set of arc-disjoint circuits in $D$, where $C_i = (v_{i,1},v_{i,2},\ldots,v_{i,r_i})$, $r_i \geq 2$, $i \in [k]$. Let $e_{i,j} = (v_{i,j},v_{i,j+1})$, for $i \in [k]$ and $j \in [r_i-1]$. Moreover, let $e_{i,r} = (v_{i,r},v_{i,1})$ for $i \in [k]$.

Let $C'_i = (e_{i,1},e_{i,2},\ldots,e_{i,r_i})$ for $i \in [k]$. Then $C'_i$ is also a circuit in $\mathcal{L}(D)$ for every $i \in [k]$. Moreover, as the circuits $C_1,C_2,\ldots,C_k$ share no common edges in $D$, we deduce that $C'_1,C'_2,\ldots,C'_k$ share no common vertices in $\mathcal{L}(D)$. Therefore, they form a set of $k$ vertex-disjoint circuits in $\mathcal{L}(D)$.

2) $\nu_0(\mathcal{L}(D)) \leq \nu_3(D)$. It suffices to show that the existence of a set of vertex-disjoint circuits in $\mathcal{L}(D)$ implies the existence of a set of arc-disjoint circuits of the same size in $D$. Let $\{C'_1,C'_2,\ldots,C'_k\}$ be a set of vertex-disjoint circuits in $\mathcal{L}(D)$, where $C'_i = (e_{i,1},e_{i,2},\ldots,e_{i,r_i})$ for $i \in [k]$. Suppose that $e_{i,j} = (v_{i,j},v_{i,j+1}) \in \mathcal{E}(D)$ for $i \in [k]$ and $j \in [r_i]$, where $v_{i,j}$ and $v_{i,j+1}$ are vertices of $D$. Then $v_{i,r_i+1} \equiv v_{i,1}$ for $i \in [k]$. For each $i \in [k]$, consider the sequence of (possibly repeated) vertices $v_{i,1},v_{i,2},\ldots,v_{i,r_i+1}$.

Since $v_{i,1} \equiv v_{i,r_i+1}$ and $(v_{i,j},v_{i,j+1}) \in \mathcal{E}(D)$ for all $j \in [r_i]$, there exist $j_0$ and $j_1$ such that
• $1 \leq j_0 < j_1 \leq r_i$;
• $v_{i,j_0} \equiv v_{i,j_1+1}$;
• $v_{i,j_0}, v_{i,j_1}$ are distinct.

Then $C_i = (v_{i,j_0}, v_{i,j_0+1}, \ldots, v_{i,j_1})$ is a circuit in $D$.
Since the circuits $C'_1, C'_2, \ldots, C'_k$ share no common vertices in $\mathcal{L}(D)$, we obtain that the circuits $C_1, C_2, \ldots, C_k$ share no common edges in $D$.

Proof of Lemma 6.6: Let $F = \{e_1, e_2, \ldots, e_k\}$, where $e_j \in \mathcal{E}(D)$ for $i \in [k]$, be an arbitrary set of arcs of $D$. We can also view $F$ as a set of vertices of $\mathcal{L}(D)$. It suffices to show that $F$ is a feedback arc set of $D$ if and only if $F$ is a feedback vertex set of $\mathcal{L}(D)$, for every such set $F$.

Let $D - F$ be the digraph obtained from $D$ by removing all arcs in $F$. Let $\mathcal{L}(D) - F$ be the digraph obtained from $\mathcal{L}(D)$ by removing all vertices in $F$. Then $\mathcal{L}(D) - F = \mathcal{L}(D - F)$. As shown in the proof of Lemma 6.5, the existence of a circuit in $D - F$ would result in the existence of a circuit in $\mathcal{L}(D - F)$ and vice versa. Therefore, $D - F$ is acyclic if and only if $\mathcal{L}(D) - F$ is acyclic. Thus, $F$ is a feedback arc set of $D$ if and only if $F$ is a feedback vertex set of $\mathcal{L}(D)$.
